### Message from the Guest Editors

Secretory proteins and membranes exit the ER into ER-derived carriers and are transported to the Golgi before being sorted and delivered to their final destinations. This task is fundamental for the maintenance and function of secretory pathway compartments as well as for extracellular environment roles. The Unfolded Protein Response pathways, which preside over the control of proteostasis within the secretory pathway, the assembly of the multiprotein complex COPII at the ER membranes, and the ER-phagy are principal actors in ER-to-Golgi trafficking control. In this Special Issue, we welcome scientific contributions that describe novel cellular mechanisms and their interconnections implicated in ER-to-Golgi trafficking control and that discuss how defects of the molecular machinery that control ER-export result in diverse human diseases. We also welcome scientific reports that show and/or discuss possible therapeutic approaches that may be used in the treatment of ER-to Golgi trafficking-based disorders.

Deadline for manuscript submissions:

**30 April 2022**
